Abstract

It is now widely recognized that human activities have reached a level that could result in abrupt and, in some cases, irreversible environmental changes detrimental to human development (Steffen et al. 2015). Societies face increasing challenges such as climate change, jeopardized food security and water resource provision, and an enhanced disaster risk.

One approach to answer these challenges is to increasingly rely on technological strategies, which are designed and managed to be as simple, replicable and predictable as possible (Hoffert et al. 2002). For instance, physico-chemical biofiltration processes are used to purify air and water at large scales in most countries, in particular in the northern hemisphere. An alternative approach is to manage the (socio-) ecological systems in a comprehensive approach in order to sustain and potentially increase the delivery of the ecosystem services (ES) to humans.1

The second approach recognizes the complexity of socio-ecological systems and the fact that they are dynamic, leaving room for self-reorganization and mutability and associated resistance and resilience capacities (Garmentani and Benson 2013). In this context, nature-based solutions (NBS) have recently been put forward by practitioners (in particular the International Union for Nature Conservation, IUCN) and quickly thereafter by policy (European Commission), referring to the sustainable use of nature in solving societal challenges.

While ES are often valued in terms of immediate benefits to human well-being and economy, NBS focus on the benefits to people and the environment itself, to allow for sustainable solutions that are able to respond to environmental change and hazards in the long-term. NBS go beyond the traditional biodiversity conservation and management principles by “re-focusing” the debate on humans and specifically incorporating societal factors such as human well-being and poverty alleviation, socio-economic development, and governance principles.

In this sense, NBS are strongly connected to ideas such as natural systems agriculture (Jackson 2002), natural solutions (Dudley et al. 2010), ecosystem-based approaches (Cowan et al. 2010), green infrastructures (Benedict and McMahon 2006), and ecological engineering (Borsje et al. 2011).2

1 In this paper, we refer to ES as the direct and indirect contributions of ecosystems to human well-being (Costanza et al. 1997, Millennium Ecosystem Assessment 2005).

2 For instance, ecosystem-based approaches are increasingly promoted for climate change adaptation and mitigation (Cowan et al. 2010, Naumann et al. 2011, Burch et al. 2014) by organisations like United Nations Environment Programme (UNEP) and non-governmental organisations such as The Nature Conservancy. Similarly, green infrastructures refers to an “interconnected network of green spaces that conserves natural systems and provides assorted benefits to human populations” (Benedict and McMahon 2006).
The concept of ecological engineering may be closest to NBS (at least types 2 and 3 below), though it has different definitions (Mitsch 2012). In particular, Barot et al. (2012) indicate that the goal of ecological engineering is to develop more sustainable practices informed by ecological knowledge with the aim to 1. protecting and 2. restoring ecological systems, 3. modifying ecological systems to increase the quantity, quality and sustainability of particular services they provide, or 4. building new ecological systems that provide services that would otherwise be provided through more conventional engineering based on non-renewable resources.3

The term “nature-based solutions” was first used in the late 2000s (MacKinnon et al. 2008, Mittermeier et al. 2008) in the context of finding new solutions to mitigate and to adapt to climate change effects whilst simultaneously protecting biodiversity and improving sustainable livelihoods. The IUCN referred to NBS in a position paper for the United Nations Framework Convention on Climate Change (IUCN 2009), after which the term has been quickly taken up by policy, viewing NBS as an innovative mean to create jobs and growth part of a green economy. Currently, the European Commission is developing a EU research and innovation programme under the Horizon 2020 Framework Programme (European Commission 2015), with the aim to position Europe as a world leader in this field.

Many Voices, One Term

The NBS idea has barely been evaluated by the scientific community (but see MacKinnon and Hickey 2009, MacKinnon et al. 2011), and different stakeholders view NBS from different perspectives. For instance, IUCN (2012) stresses that they “can deliver effective solutions to major global challenges, such as climate regulation, using nature while providing biodiversity benefits in terms of diverse, well-managed ecosystems and respecting and reinforcing communities’ rights over natural resources”. This framing puts biodiversity and local human communities at the heart of NBS. In the context of the on-going political debate on jobs and growth (main drivers of the current EU policy agenda), the European Commission underlines that NBS can transform environmental and societal challenges into innovation opportunities, by turning natural capital into a source for green growth and sustainable development. For the commission, NBS are sustainable measures that aim to simultaneously meet environmental, societal and economic objectives, which should help maintain and enhance natural capital (European Commission 2015). This framing puts economy and social assets at the heart of NBS while sustaining environmental conditions. In any case, NBS are often seen as a concept, and more likely a flagship term, that can provide incentives for governments, institutions, business and citizens to develop innovative ways to integrate natural capital in policies and planning, and to maintain or increase biodiversity and human well-being (European Commission 2015).

With this paper, we do not intend to provide an in-depth review of all concepts related to NBS, nor to nail down a strict definition. Rather, we aim to sharpen the term, in particular by proposing a typology of NBS, and reflect on its added value with respect to existing terms and concepts, its possible drawbacks in case of misuse, and perceived future challenges for research and management. As such, we hope to spur further discussion, and contribute to sharpening the term allowing for a better evaluation of its true potential.

A Proposed Typology

We propose a typology characterizing NBS along two gradients (figure 1): 1. “How much engineering of biodiversity and ecosystems is involved in NBS?”, 2. “How many ecosystem services and stakeholder groups are targeted by a given NBS?”. Due to the ES trade-offs that likely exist (Howe et al. 2014), we hypothesize that most often, the higher the number of services and stakeholder groups is targeted, the lower the capacity to maximize the delivery of each service and simultaneously fulfill the specific needs of all stakeholder groups will be. As such, there are three types of NBS:

- **Type 1** consists of no or minimal intervention in ecosystems, with the objectives of maintaining or improving the delivery of a range of ES both inside and outside of these preserved ecosystems. Examples include the protection of mangroves in coastal areas to limit risks associated to extreme weather conditions and to provide benefits and opportunities to local populations; and the establishment of marine protected areas to conserve biodiversity within these areas while exporting biomass into fishing grounds (Grundel-Colvert et al. 2014). This type of NBS is connected to, e.g., the concept of biosphere reserves incorporating core protected areas for nature conservation and buffer and transition areas where people live and work in a sustainable way.

- **Type 2** corresponds to the definition and implementation of management approaches that develop sustainable and multifunctional ecosystems and landscapes (extensively or intensively managed), which improves the delivery of selected ES compared to what would be obtained with a more conventional intervention. Examples include innovative planning of agricultural landscapes to increase their multifunctionality; and approaches for enhancing tree species and genetic diversity to increase forest resilience to extreme events. This type of NBS is strongly connected to concepts like natural systems agriculture (Jackson 2002), agro-ecology (Altieri 1989), and evolutionary-oriented forestry (Lefèvre et al. 2014).

- **Type 3** consists of managing ecosystems in very intrusive ways or even creating new ecosystems (e.g., artificial ecosystems with

---

3 Terms such as “ecosystem restoration” (return of an ecosystem to a close approximation of its condition prior to a disturbance or period of specific management) are often seen as part of ecological engineering (National Research Council 1992). The same applies for “agro-ecology” which delineates the ecological principles necessary to develop sustainable agricultural production systems (Altieri 1989).
(NBS) approaches. Three main types of NBS are defined, differing in the level of engineering or management applied to biodiversity and ecosystems (x-axis), and in the number of services to be delivered, the number of stakeholder groups targeted, and the likely level of maximization of the delivery of targeted services (y-axis). Some examples of NBS are located in this schematic representation. Note that the y-axes could be shifted, and that type 3 cannot be viewed as “better” than type 1, the three types being complementary.

New assemblages of organisms for green roofs and walls to mitigate city warming and clean polluted air. Type 3 is linked to concepts like green and blue infrastructures (Benedict and McMahon 2006) and objectives like restoration of heavily degraded or polluted areas. Within this type, novel approaches such as animal-aided design (Hauck and Weisser 2015) are currently being explored to bridge the gap between biodiversity conservation and landscape architecture.

Type 1 fully fits with the way IUCN frames NBS. Types 2 and 3 would also fit with this definition providing that they should contribute to preserving biodiversity and managing or restoring ecosystems sustainably while delivering a range of ES. In the case of agro-ecosystems or inner city green spaces, e.g., it would be important to consider ecological complexity and connection with surrounding ecosystems to provide biodiversity benefits. Type 2 and moreover type 3 are often exemplified by the European Commission for turning natural capital into a source for green growth and sustainable development.

The boundary between these three types is obviously not clear-cut. Hybrid solutions exist along this gradient both in space and time. For instance, at landscape scale, mixing protected and managed areas could be needed to fulfill multifunctionality and sustainability goals. Similarly, a constructed wetland can be developed as a type 3 but, when well established, may subsequently be preserved and surveyed as a type 1.

Outlier examples (that would plot upper-left and bottom-right) are likely rare. Pristine ecosystems, like taiga, have many roles at local and global scale (like water and climate regulation, support to livelihoods of local populations, etc.), and may therefore not be restricted to a narrow range of stakeholders. Similarly, although abilities to manage complex ecosystems will continue to increase over the coming decades, the design of artificial ecosystems will likely target only a few ES and have to tackle ES trade-off.

### Opportunities and Risks Associated to NBS

**What NBS are, or are not**

While we advocate that the open nature of the term NBS can favor its success, we contend that it is important to specify which solutions should and should not be considered as NBS. We illustrate this with the development of green roofs and walls in cities. Having in mind the sole objective of developing green surfaces in urban areas to mitigate the effects of global warming, green roofs or walls could be created using, e.g., clones from one or very few plant species, regardless of their biogeographical distribution. Such new structures would hardly contribute to increase biodiversity and the delivery of other ES. This may also lead to a poor resistance and resilience to future extreme events, increased management costs, and risk of biological invasions. Furthermore, without a coordinated approach at the city scale, firms would likely design green buildings in a case-by-case approach with a very uncertain effectiveness at city scale. Such an approach, which largely misses out on the objectives of sustainability, increased biodiversity, and effectiveness at relevant scale (here the city), would not fit the NBS framing. Similarly, rain gardens designed to manage storm water runoff that pay little reference to what plants are used and to other ES, fall short of NBS. In contrast, within an urban planning approach at the city scale, a range of species could be selected for green roofs or walls based on their biogeography and key functional traits (Lundholm et al. 2015), which would address multiple goals such as cooling during summer, storm water capture, pollution abatement, increased human well-being, biodiversity enhancement, and better resilience to future hazards, while adopting adequate governance to properly tackle the issue at city scale (figure 2, p. 247). Such approaches would fit the NBS term. NBS thus broadens the ES framework, promoting and better relying on biological diversity to increase the resistance and resilience of social-ecological systems to global changes and extreme or unexpected events and the delivery of a range of ES.

**Calling for innovative NBS should not imply loosing track of existing ones**

NBS are often referred to as innovative, but they should not include exclusively “new” solutions. Whilst the NBS concept offers new opportunities and brings added-value, it also encompasses existing ideas and requires inclusion of lessons from the past. Local and traditional knowledge should also be considered when exploring NBS. Traditional management systems (e.g., for agriculture, forestry, aquaculture, fishing) and their principles should be reassessed in light of NBS criteria, as they often include sustainable, locally-adapted and biodiversity-enhancing practices. For example, engineered biodiverse pastures developed in Portugal in the 1960s and 1970s provide higher yields of better quality forage, significantly increase sustainable stocking rates, and have mult-

tiple environmental co-benefits (Teixeira et al. 2015). This could be a typical NBS unrecognized as such so far.

**NBS should exploit win-win situations but will have to cope with trade-offs and uncertainties**

NBS should account for multiple interests (in particular environmental, societal, and economic ones) and promote sustainability. Yet, there will be few win-win situations where all goals are simultaneously met. Documenting and analyzing the possible synergies and trade-offs between ES and stakeholders’ expectations will therefore be at the heart of identifying and implementing NBS. In addition, stakeholders and policy makers must remain aware of the complexities and uncertainties that surround NBS. Assessing the risks associated with a given NBS should be compulsory and alternative solutions should be envisaged, looking at the potential impacts through time and space, and accounting for future environmental changes. Otherwise, NBS could generate problems instead of solutions (e.g., species introduced for pest control can become invasive, if corresponding controls are lacking).

**NBS could help meet various ethical, intellectual and relational challenges**

NBS clearly build on, and share aspects with other concepts, approaches and tools, but might be more holistic and have more potential to support environmental sustainability. More specifically, the NBS approach may help meet three types of challenges – ethical, intellectual, relational – that other concepts have not completely addressed so far (Jones 2011; but see Hauck et al. 2013).

**Ethical challenges** arise at two different levels: NBS are 1. a human-centered utilitarian concept, and 2. include other knowledge systems beyond modern science (i.e., indigenous and local knowledge). As the NBS term clearly refers to societal challenges (ontological dimension), problems defined by humans (epistemic dimension), and the sustainable use of nature (practical dimension), there is no doubt that the concept is anthropocentric as are other current concepts such as ES. The debate on anthropocentric and bio- or ecocentric (assuming an intrinsic value of living beings, entire ecosystems, or the biosphere) views has been at the heart of the discussions on “the new conservation” (Kareiva et al. 2015) and the discussion on “the new conservation” (Kareiva 2014); we will not start it again here. We advocate that NBS might help to demonstrate that these two views can be complementary, leading to successful approaches to promote biodiversity. The second ethical challenge relates to the plurality of value and knowledge systems that exist among different cultures regarding human-nature interactions. This plurality of views has to be acknowledged and integrated while developing and assessing NBS, and stakeholder participation has to be ensured. NBS have the potential to solve or avoid conflicts here, because they aim at dealing with concrete problems often at a local level. Moreover, research has shown that a mismatch exists between ES approaches and governance needs (Prammer and Furman 2012) and that transdisciplin ary approaches are more likely to achieve effective change on the ground (BIOMOT 2014).

**The intellectual challenge** requires those coming from various traditional ecosystems and science, ecology, conservation and restoration, forestry and agronomy, sociology, economics, architecture, etc.) to respectively identify and fuse their key principles into a coherent, useful set that is comprehensible and accessible to all. The nature of NBS could help with providing the critical intellectual mass and rapid cross-fertilization of ideas needed for reaching this ambition. Moreover, there is a need to promote research models where applied and fundamental sciences are not opposed, thereby facilitating transdisciplinarity (Barot et al. 2015).

**The relational challenge** is strategic. Being promoted by practitioners and policy makers rather than scientists (unlike, e.g., ES: Gömez-Baggethun et al. 2009), one added-value of the NBS term could be that it is easier to grasp by non-technical audiences and key societal partners (business, policy, education, and practitioners), and hence could promote the stakeholder model of research (Barot et al. 2015), receive wider support, and result in systemic solutions rather than sectorial ones. Although many practitioners and scientists working in traditional fields such as agriculture, forestry and aquaculture are genuinely concerned by sustainability issues, they often have difficulties integrating scientific ecological knowledge and turning towards drastically new practices (Neßhöver et al. 2013, Lewinsohn et al. 2015). Work on NBS could mobilize a great number of people towards achieving environmental sustainability in all kinds of socio-ecosystems. However, while social scientists and various groups of stakeholders may receive the idea of NBS well, its acceptance among natural scientists, in particular those involved in species and habitat conservation, remains a challenge as there is some distrust in “yet another buzz word” and concern that at the end these NBS may address biodiversity conservation only in a cosmetic manner, possibly generating even more pressure on natural systems.

For their successful deployment, we believe that NBS should not be considered as “the one and only” possible way, but need to be embedded in a wider, coherent strategy at research and policy level. Otherwise, NBS run the risk of misinterpretation, misapplication and non-acceptance. One of the risks is that it might channel all research and management efforts towards an approach that is useful in some but not all conditions, whereas nature preservation – and associated research – should be supported also.

The authors thank all the participants of the horizon scanning workshop organized in June 2014 by the BiodivERsA ERA-NET. Various stakeholders (scientists, policy makers, non-governmental organizations, research programmers and funders) were asked to exchange their views on the emerging NBS term. The authors also thank Rachel Armstrong (University of Newcastle) for insightful discussion. BiodivERsA is the network of national and local organizations that program, fund, and promote pan-European research on biodiversity and ecosystem services. It was supported by the European Commission in the Seventh Framework Programme, and is further supported from 2015 under the ERA-NET cofund scheme in Horizon2020. First and last authors (Hilde Eggermont and Xavier Le Roux) contributed equally to this paper.
